**1.** Suppose your training examples are sentences (sequences of words). Which of the following refers to the  $j^{th}$  word in the  $i^{th}$  training example?

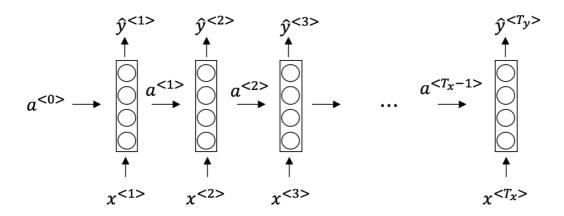

1 / 1 punto

- $(x^{(i) < j > j})$
- $\bigcap x^{< i > (j)}$
- $(\gamma^{(j) < i})$
- $\bigcap x^{< j > (i)}$ 
  - ✓ Correcto

We index into the  $i^{th}$  row first to get the  $i^{th}$  training example (represented by parentheses), then the  $j^{th}$  column to get the  $j^{th}$  word (represented by the brackets).

2. Consider this RNN:

1 / 1 punto

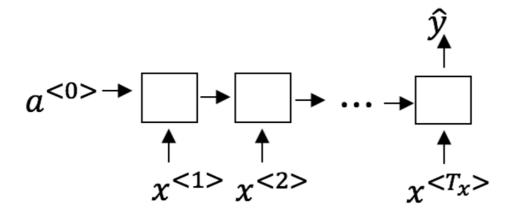

This specific type of architecture is appropriate when:

- $T_x = T_y$
- $\bigcap T_x < T_y$
- $\bigcap T_x > T_y$
- O  $T_x = 1$ 
  - ✓ Correcto

It is appropriate when every input should be matched to an output.

**3.** To which of these tasks would you apply a many-to-one RNN architecture? (Check all that apply).

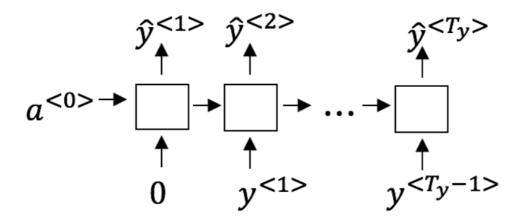

1 / 1 punto

- ☐ Speech recognition (input an audio clip and output a transcript)
- Sentiment classification (input a piece of text and output a 0/1 to denote positive or negative sentiment)
  - ✓ Correcto
    Correct!
- ☐ Image classification (input an image and output a label)
- Gender recognition from speech (input an audio clip and output a label indicating the speaker's gender)
  - Correct!

1/1 punto

4. You are training this RNN language model.

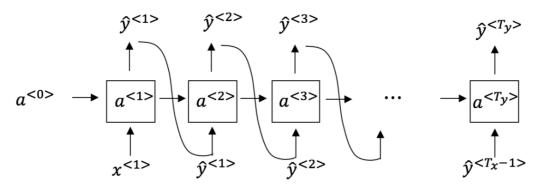

At the  $t^{th}$  time step, what is the RNN doing? Choose the best answer.

- O Estimating  $P(y^{<1>}, y^{<2>}, \dots, y^{<t-1>})$
- $\bigcirc \text{ Estimating } P(y^{< t >})$
- **(a)** Estimating  $P(y^{< t>} | y^{< 1>}, y^{< 2>}, \dots, y^{< t-1>})$
- O Estimating  $P(y^{< t>} | y^{< 1>}, y^{< 2>}, \dots, y^{< t>})$

Yes, in a language model we try to predict the next step based on the knowledge of all prior steps.

**5.** You have finished training a language model RNN and are using it to sample random sentences, as follows:

1 / 1 punto

What are you doing at each time step *t*?

	0	(i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as $\hat{y}^{}$ . (ii) Then pass the ground-truth word from the training set to the next time-step.	
	0	(i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as $\hat{y}^{< t>}$ . (ii) Then pass the ground-truth word from the training set to the next time-step.	
	0	(i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as $\mathcal{Y}^{< t>}$ . (ii) Then pass this selected word to the next time-step.	
	•	(i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as $\hat{y}^{}$ . (ii) Then pass this selected word to the next time-step.	
	(	Correcto Yes!	
6.	tak	u are training an RNN, and find that your weights and activations are all ing on the value of NaN ("Not a Number"). Which of these is the most likely use of this problem?	1 / 1 punto
	0	Vanishing gradient problem.	
	•	Exploding gradient problem.	
	0	ReLU activation function g(.) used to compute g(z), where z is too large.	
	0	Sigmoid activation function $g(.)$ used to compute $g(z)$ , where $z$ is too large.	
	(	Correcto	
7.	are	ppose you are training a LSTM. You have a 10000 word vocabulary, and using an LSTM with 100-dimensional activations $a^{<\!\!\!/}$ . What is the nension of $\Gamma_u$ at each time step?	1 / 1 punto
	0	1	
	•	100	
	0	300	

- 10000
  - ✓ Correcto

Correct,  $\Gamma_u$  is a vector of dimension equal to the number of hidden units in the LSTM.

8. Here're the update equations for the GRU.

1 / 1 punto

## GRU

 $a^{< t>} = c^{< t>}$ 

$$\tilde{c}^{} = \tanh(W_c[\Gamma_r * c^{}, x^{}] + b_c)$$

$$\Gamma_u = \sigma(W_u[c^{}, x^{}] + b_u)$$

$$\Gamma_r = \sigma(W_r[c^{}, x^{}] + b_r)$$

$$c^{} = \Gamma_u * \tilde{c}^{} + (1 - \Gamma_u) * c^{}$$

Alice proposes to simplify the GRU by always removing the  $\Gamma_u$ . I.e., setting  $\Gamma_u$  = 1. Betty proposes to simplify the GRU by removing the  $\Gamma_r$ . I. e., setting  $\Gamma_r$  = 1 always. Which of these models is more likely to work without vanishing gradient problems even when trained on very long input sequences?

- $\bigcirc$  Alice's model (removing  $\Gamma_u$ ), because if  $\Gamma_r \approx 0$  for a timestep, the gradient can propagate back through that timestep without much decay.
- O Alice's model (removing  $\Gamma_u$ ), because if  $\Gamma_r \approx 1$  for a timestep, the gradient can propagate back through that timestep without much decay.
- **(a)** Betty's model (removing  $\Gamma_r$ ), because if  $\Gamma_u \approx 0$  for a timestep, the gradient can propagate back through that timestep without much decay.
- O Betty's model (removing  $\Gamma_r$ ), because if  $\Gamma_u \approx 1$  for a timestep, the gradient can propagate back through that timestep without much decay.
  - **⊘** Correcto

Yes. For the signal to backpropagate without vanishing, we need  $c^{< t>}$  to be highly dependant on  $c^{< t-1>}$ .

9. Here are the equations for the GRU and the LSTM:

1/1 punto

GRU

LSTM

$$\tilde{c}^{} = \tanh(W_c[\Gamma_r * c^{}, x^{}] + b_c)$$

$$\tilde{c}^{} = \tanh(W_c[a^{}, x^{}] + b_c)$$

$$\Gamma_u = \sigma(W_u[c^{}, x^{}] + b_u)$$

$$\Gamma_u = \sigma(W_u[a^{}, x^{}] + b_u)$$

$$\Gamma_r = \sigma(W_r[c^{}, x^{}] + b_r)$$

$$\Gamma_f = \sigma(W_f[a^{}, x^{}] + b_f)$$

$$C^{} = \Gamma_u * \tilde{c}^{} + (1 - \Gamma_u) * c^{}$$

$$\Gamma_o = \sigma(W_o[a^{}, x^{}] + b_o)$$

$$C^{} = \Gamma_u * \tilde{c}^{} + \Gamma_f * c^{}$$

$$C^{} = \Gamma_u * \tilde{c}^{} + \Gamma_f * c^{}$$

$$C^{} = \Gamma_u * \tilde{c}^{} + \Gamma_f * c^{}$$

$$C^{} = \Gamma_u * \tilde{c}^{} + \Gamma_f * c^{}$$

From these, we can see that the Update Gate and Forget Gate in the LSTM play a role similar to \_\_\_\_\_ and \_\_\_\_ in the GRU. What should go in the the blanks?

- $\bullet$   $\Gamma_u$  and  $1 \Gamma_u$
- $\bigcap \Gamma_u$  and  $\Gamma_r$
- $\bigcap$  1  $\Gamma_u$  and  $\Gamma_u$
- $\bigcap \Gamma_r$  and  $\Gamma_u$ 
  - ✓ Correcto
    Yes, correct!
- **10.** You have a pet dog whose mood is heavily dependent on the current and past few days' weather. You've collected data for the past 365 days on the weather, which you represent as a sequence as  $x^{<1>}, \ldots, x^{<365>}$ . You've also collected data on your dog's mood, which you represent as  $y^{<1>}, \ldots, y^{<365>}$ . You'd like to build a model to map from  $x \to y$ . Should you use a Unidirectional RNN or Bidirectional RNN for this problem?
  - Bidirectional RNN, because this allows the prediction of mood on day t to take into account more information.
  - Bidirectional RNN, because this allows backpropagation to compute more accurate gradients.
  - Unidirectional RNN, because the value of  $y^{< t>}$  depends only on  $x^{< 1>}, \dots, x^{< t>}$ , but not on  $x^{< t+1>}, \dots, x^{< 365>}$
  - O Unidirectional RNN, because the value of  $y^{< t>}$  depends only on  $x^{< t>}$ , and not other days' weather.
